THE BENEFITS OF CLIL INSTRUCTION IN SPANISH STUDENTS’ PRODUCTIVE VOCABULARY KNOWLEDGE

Andrés Canga Alonso
Mario Arribas García
Universidad de la Rioja

Abstract
This paper aims at (i) investigating the productive vocabulary knowledge of 101 10th grade (4th ESO) EFL Spanish students in two different types of instruction CLIL and non-CLIL, and (ii) analysing the results obtained according to sex-based differences among the participants. We used the parallel version of the Productive Vocabulary Levels Test (PVLT) (Laufer & Nation, 1995, 1999) to measure students’ productive vocabulary knowledge. Our results reveal that our CLIL sample obtained significantly better results than their non-CLIL partners, and the students’ productive vocabulary size ranks below 1,000 words. As for sex-based differences, CLIL boys’ mean scores are the highest, but the differences between both sexes, regardless of their type of instruction, are not statistically significant. These findings led us to believe that the CLIL approach offers a benefit for productive vocabulary learning in a foreign language.

Keywords: Secondary Education, productive vocabulary, CLIL, non-CLIL, sex differences.

1. Introduction

Vocabulary is acknowledged to be of paramount importance in foreign language learning (FLL). Hence, examining learners’ word knowledge can provide interesting and reliable insights into their overall language knowledge. In recent decades, several studies have analysed the receptive vocabulary knowledge of EFL learners following an approach based on Content and Language Integrated Learning (CLIL), i.e. learning a content subject other than language lessons through the foreign language and traditional EFL (non-CLIL) instruction (Canga Alonso, 2013 a, b; Nikula, Dalton-Puffer & Lлинаres, 2013; Ruiz de Zarobe, 2011; Coyle, Hood & Marsh, 2010; Jiménez Catalán and Ruiz de Zarobe, 2009; Jiménez Catalán, Ruiz de Zarobe & Cenoz, 2006). However, to our
knowledge, there is a scarcity of research concerning productive vocabulary knowledge in CLIL and non-CLIL instruction at secondary school level in Spain. The main purpose of this paper is to compare general productive vocabulary size of traditional EFL and CLIL learners since it is generally believed that words are known receptively first and only after intentional or incidental learning become available for productive use. CLIL learners have a longer exposure to the foreign language, thus, the present research wants to prove that this exposure fosters productive vocabulary learning and CLIL subjects obtain better results in the Productive Vocabulary Levels Test (PVLT) (Laufer & Nation, 1995, 1999).

The study also explores differences in productive vocabulary knowledge of male and female students. Recent studies on sex-based differences and vocabulary learning have not reached an agreement to assert that one sex outperforms the other as far as receptive and productive word knowledge is concerned. Thus, our findings will aim to shed some light on this aspect by comparing the scores obtained by male and female students in response to the PVLT. Hence, we review the main studies dealing with the importance of vocabulary knowledge and sex-based differences and explore the relationship between CLIL and foreign language vocabulary. A report of the study conducted with its methodology, main results found and interpretation of those results follows. The paper concludes by pointing out some lines for further research trying to overcome the main limitations of the present study.

2. Vocabulary Knowledge and sex variables in foreign language learning

A large vocabulary size is essential to interacting in a foreign language. In this sense, researchers have tackled the issue concerning the number of words necessary to understand spoken discourse (Adolphs & Schmitt, 2004; Nation, 2001) and to read and comprehend texts in the native and foreign language (Laufer, 1997; Anderson & Freebody, 1981). Among the former researchers, Adolphs & Schmitt (2004) estimated that, at least, 2,000 word forms have to be mastered in order to understand around 90% and 94% of spoken discourse in different contexts. Among the latter, Laufer (1992, 1997) stated that a text coverage of 95% can be reached with a 5,000-word English vocabulary or 3,000 word families, which agrees with the assertions made by Hazenberg & Hulstijn (1996), Nation (1993, 2001) and Cobb & Horst (2004). More recently, Nation (2006) asserted that 8,000 to 9,000 word families are needed for understanding a written text and a vocabulary of 6,000 to 7,000 word families for comprehension of spoken texts, if 98% coverage of a text is desired. Hirsh & Nation (1992) also pointed out that knowledge of 5,000 word families is necessary to enjoy reading. Estimates based on word frequency criteria have been calculated and research claims that gaining command of the 2,000-3,000 most frequent words as soon as possible is vital for the language learner to communicate orally and in written form in the foreign language (Milton, 2009; Nation & Waring, 1997; Nation, 1993). The sooner the most frequent words are learned by students, the better their language performance will be. As Schmitt claims: “The learning of these basic words cannot be left to chance, but should be taught as quickly as possible, because they open […] the door of further learning” (2000: 137).

As it has been mentioned, vocabulary size is one of the central dimensions in explorations of lexical proficiency. Different studies have set to the task of finding estimations of productive and
receptive vocabulary size. The tests designed for this purpose are generally built upon frequency lists (Nation, 1990, 2001) on the assumption that knowledge of less frequent words implies knowledge of more frequent words (Schmitt, 2000). Based on this idea of finding estimations of productive word knowledge, several instruments have been designed to measure productive vocabulary size. One of the most frequently used tests is Lex30 (Meara & Fitzpatrick, 2000). It is a free word association task which assesses discrete, comprehensive and context-independent vocabulary. It has several practical advantages since it generates a rich vocabulary output very economically, that is, through single word prompts. It is easily administered and it requires very little time to complete (15 minutes); and it is scored automatically using a computer programme (Jiménez Catalán & Moreno Espinosa, 2005). This test has been implemented in primary education (Moreno Espinosa, 2009; Jiménez Catalán & Moreno Espinosa, 2005) and with undergraduates (Fitzpatrick & Meara, 2004, Jiménez Catalán & Moreno Espinosa, 2004). However, it presents some methodological problems when classifying the words that the Lex30 scorer did not recognize in their appropriate bands (Jiménez Catalán & Moreno Espinosa 2005).

Another instrument which has been used widely to explore students’ productive vocabulary knowledge is the Productive Vocabulary Levels Test (PVLT) (Lauffer & Nation, 1995, 1999). The PVLT addresses two dimensions of lexical competency: partial productive word knowledge and word frequency. It measures discrete, selective and context dependent vocabulary (Mochizuki, 2012; Moreno Espinosa, 2010). One of the advantages of the test is that frequency bands are independent from one another, which allows researchers to give their testees either the whole test or only the bands that are suitable for their learners’ level. This fact together with its format (see Appendix I) seems to be appropriate for secondary school students. Nevertheless, this test has not been as widely implemented as its receptive version (Schmitt, Schmitt & Clapham 2001), which has been used to test primary (Agustín Llach & Terrazas Gallego, 2012; Terrazas Gallego & Agustín Llach, 2009; Jiménez Catalán & Terrazas Gallego, 2005-2008) and secondary school (Canga Alonso, 2013a) Spanish students’ receptive vocabulary knowledge in traditional EFL instruction.

Considering these facts, it was decided that the PVLT is a good test to explore the productive vocabulary size of the sample of Spanish EFL learners in the last year of secondary school for two main reasons: it measures discrete, context dependent vocabulary, and it allows for profiling learners’ vocabulary size on the basis of the frequency level to which the words used belong. Hence, the main aim of the present paper is to explore 10th grade Spanish students’ productive vocabulary size in CLIL and non-CLIL instructional contexts, using the PVLT as the instrument of measurement.

Having analysed the importance of vocabulary in L2 learning as well as having referred to the research conducted on vocabulary learning, the importance of sex-based differences in the literature on vocabulary learning can be considered. The role of sex has also occupied an outstanding place in current research on vocabulary in a FL. Receptive and productive vocabulary knowledge of male and female learners has been widely examined, and scholars have reached different conclusions. Boyle (1987) concludes that, exception to what, boys are superior to girls in the comprehension of heard vocabulary. Similarly, Scarcella & Zimmerman (1998) found that men performed significantly better than women in a test of academic vocabulary recognition, understanding and use. In Lynn, Fergusson, & Horwood (2005), and Edelenbos & Vinjé (2000), males also outperformed females in vocabulary

In the same vein, in a recent longitudinal research Agustín Llach & Terrazas Gallego (2012) found very slight differences among males and females across grades in the context of Spanish primary education concerning their receptive vocabulary knowledge. Canga Alonso (2013b) also found slight differences in his study of primary and secondary school students’ receptive vocabulary. On the contrary, highly significant differences were found in favour of females in the mean number of words produced in response to the 15 cues of a lexical availability test (Jiménez Catalán & Ojeda Alba, 2009). A set of recent studies compiled in Jimenez Catalán (2010) also pointed to mixed results on sex differences or tendencies. In this same volume, García Gómez (2010) explored the development of gender relations and identities through analysis of writing samples from Spanish male and female EFL university students, and his findings revealed male and female gender-biased subjacent ideologies. As Sunderland (2010) claims, a careful analysis of this compilation provides the conclusion that the relationships between vocabulary and gender are not enduring, but may be context and test type-specific. These relationships can also be influenced by L1, age or L2 proficiency since the studies previously referred to show a variety of results depending on the context (Spain and abroad), type of instruction (CLIL/non-CLIL) and even among learners when the same test is applied to students from the same learning context.

Considering the aforementioned studies, it can be stated that results are inconclusive regarding the role of sex in foreign language learning and in particular in lexical acquisition. Furthermore, the type of word knowledge explored, the learning context, or the task used for data gathering seem to play a relevant role in the establishment of sex tendencies. For this reason, the present study tries to ascertain if the scores obtained by male and female students in the PVLT are alike since no difference has been made in the formal instruction they received either with a CLIL or a non-CLIL approach as both high schools mix boys and girls in the same classroom.

3. CLIL and vocabulary learning

As mentioned in the introduction, CLIL implies the teaching of a content subject through English. Thus, its essence is integration with a dual focus: “language learning is included in content classes (e.g. maths, history, geography […], etc), and content from subjects is used in language learning classes” (Mehisto, Marsh & Frigols, 2008: 11). CLIL also provides real and meaningful input for the learner in form of subject content and language for classroom management (Muñoz, 2007).

Assuming that in CLIL settings it is necessary to progress systematically in pupils’ content and language learning and use, vocabulary knowledge is of paramount importance in order to encourage communication in the classroom. Feedback is also integrated into classroom discourse to encourage interaction among apprentices. Thus, the challenge in a CLIL setting is that trainees need to engage in dialogic interactions by using the vehicular language. As a result of this interaction, Dalton-Puffer
(2007, 2008) reports that there are some areas where clear gains are observed in CLIL classrooms such as e.g. receptive skills, vocabulary, morphology, and creativity.

Vocabulary size follows a systematic order related to frequency, since at the lowest levels of proficiency, learners are familiar with the most frequent words. But, as their experience with the FL increases, less frequent words are incorporated into the lexicon (Milton 2009; Vermeer 2001; Barrow Nakanishi, & Ishino, 1999). Therefore, it seems evident that a content-based approach provides more opportunities to learn, either explicitly or implicitly, target vocabulary in meaningful situations (Pérez-Vidal, 2009; Muñoz, 2007), since learners are exposed to the target language for a longer period than students’ enrolled in traditional EFL classrooms. Xanthou (2011) proved that CLIL had a positive impact in a group of primary school children in Cyprus regarding students’ vocabulary tests results which demonstrates that by attaching words to their surroundings, the likelihood of comprehension and retention is increased. These gains in receptive vocabulary size align with other research conducted in Spain (Jiménez Catalán & Ruiz de Zarobe, 2009; Jiménez Catalán, Ruiz de Zarobe & Cenoz, 2006), where significant results were obtained in favour of the CLIL group in receptive vocabulary knowledge. In a similar study, Canga Alonso (2013a) found statistically significant differences between 6th grade primary students in CLIL contexts and those enrolled in a traditional EFL approach. Nevertheless, to our knowledge, there is a lack of research in productive vocabulary knowledge in CLIL and non-CLIL types of instruction using the PVLT in Spanish secondary school. For these reasons and the aspects mentioned in the previous section, this study aims at (i) investigating the productive vocabulary knowledge of 15-16 year-old male and female Spanish students learning English in Spanish 10th grade (4th ESO) in relation to: ii) type of instruction (CLIL vs. non-CLIL) and iii) sex-based differences. Thus, the researchers set out to find answers to the following research questions:

1. What is the productive vocabulary knowledge of 10th grade EFL learners in CLIL and non-CLIL instruction?
2. Are there any statistically significant differences in productive vocabulary sizes between CLIL and non-CLIL learners?
3. Do we find statistically significant differences in students’ performance with regard to sex in the Productive Vocabulary Levels Test?

4. Method

4.1 Participants

Two student samples constitute the participants of this study. The CLIL group, is made up of 73 learners (37 boys and 36 girls), whereas the traditional or non-CLIL group, comprises 38 learners (26 boys and 12 girls). Both groups learn English as a curricular subject in the same grade of secondary education. (4th ESO/10th Grade). They have been learning English as a school subject since the 1st year of primary education in two weekly sessions of 50 to 60 minutes. Additionally, the CLIL group has been receiving extra-exposure to English since their 7th grade (1st year of Secondary Education).

The sample is homogeneous in regards to their socio-economic and cultural background, since participants were drawn from two high schools in the same area. Students also shared Spanish as their
native language (L1). The groups differ in the kind of instruction they received, i.e. CLIL vs. non-CLIL, and consequently, in the number of hours of exposure to English FL. Learners in the non-CLIL group were exposed to English through the English FL school subject, exclusively. However, learners in the CLIL group received, apart from the weekly EFL lessons, input in Natural Sciences and Arts and Crafts through the medium of English. Consequently, not only the amount but also the nature of the input differs between the traditional and the CLIL group. Traditional learners have received approximately 1,049 hours of exposure to EFL on a yearly basis since 1st grade of primary. The CLIL group has received the same 1,049 hours plus 30-60 more hours in CLIL.

Table 1 illustrates the approximate number of hours of exposure students have received by the time of data collection.

### 4.2 Data Collection

The 2,000 word parallel version (version A+ version C) of the Productive Vocabulary Levels Test (PVLT) (see Appendix 1) was used to measure the productive vocabulary knowledge of these subjects (Laufer & Nation 1999; Laufer & Nation 1995). The test measures knowledge of vocabulary at the 2,000, 3,000, 5,000 and 10,000 word bands (e.g. the 2000 word band would test words 1 – 2,000). The word bands correspond to the 2,000 and so on most frequent words in English which are based on West’s (1953) General Service List and the Thorndike & Lorge’s list (1944). We have chosen the 2,000 band of the test since as mentioned in section one, gaining command of the 2,000 most frequent words as soon as possible is vital for the language learner to communicate orally and in written form in the foreign language (Milton, 2009; Nation, 1993; Nation & Waring, 1997). The PVLT measures controlled productive knowledge (Laufer, 1998) since test-takers have to complete a missing word in 30 different sentence contexts where they are given the first letters of the target word as a cue. Therefore, the PVLT is a reliable, valid and practical measure of vocabulary growth (Laufer & Nation, 1999: 44). Completing the test requires the knowledge of meaning, form, phonological aspect and collocations of the target word. In addition, reading comprehension is required in gaining the clues to complete the task.

Data was collected in one session during school time. The time allotted to complete the task was 10 minutes. At the beginning of the test, clear instructions together with an example were given both orally and in written form in the students’ L1 to clarify what they were being asked to do.

Tests were corrected and total scores obtained. 0 was the minimum score and 30 was the maximum. Estimations in words were also obtained. In order to calculate students’ word estimates, Nation’s formula “Vocabulary size = N correct answers multiplied by total N words (the relevant word list divided by N items in test)” (Nation, 1990: 78) was applied. In order for an answer to be
correct, the word has to be both grammatically and orthographically adequate, e.g. if the missing word is a verb, it has to be written in the corresponding tense. Therefore, a wrong verb tense would get 0 points in that given sentence.

The sample was also analysed with SPSS 19 to check whether there were statistically significant differences according to type of instruction, sex and productive vocabulary knowledge.

5. Results

Regarding our first research question (What is the productive vocabulary knowledge of 10th grade EFL learners in CLIL and non-CLIL instruction?) the data (see table 2) revealed that the maximum score in the sample was twenty-nine points out of thirty which was attained by one of the students in the CLIL group whereas the minimum score (zero out of thirty) was achieved by one participant in the non-CLIL group. These figures indicate that students are behind from learning the 2,000 most frequent words according to the frequency lists collected by Kucera & Francis (1967), West (1953), and Thorndike & Lorge (1944). The data also implies that students can have problems understanding spoken and written discourse in English since they need to have gained at the least the 2,000 most frequent words in order to communicate orally and in written form in the foreign language (Nation & Waring, 1997). Mean scores are also higher in favour of the CLIL group (12.19 vs. 9.6) but standard deviations are quite similar for both cohorts (4.9 vs.5). This implies that the variability of results is quite alike for both groups.

Table 2. PVLT 2,000 results.

This profile is illustrated in the rankings of percentages summarized in figure 1. The results show that our CLIL informants obtained better results than our non-CLIL students in all the ranks but the lowest (0-5). It is also noteworthy that both groups of students attained similar scores in the 6-10 and 11-15 ranks, although CLIL students performed slightly better. These two ranks (6-10 and 11-15) are also the ones with the highest percentages for both cohorts. On the contrary, the raking 26-30 is quite low in the CLIL group and shows no evidence in the non-CLILs.
The benefits of CLIL instruction in Spanish students’ productive vocabulary knowledge
Andrés Canga Alonso y Mario Arribas García  Encuentro 24  ISSN 1989-0796, pp. 15-31

As for the second research question (Are there any statistically significant differences in productive vocabulary sizes between CLIL and non-CLIL learners?), students’ scores were translated into the number of known words for each frequency level applying Nation’s formula (1990: 78). As illustrated in table 3, the means obtained by the CLIL group confirms our previous presupposition on a two-fold basis: CLIL learners recognized and produced a higher number of words (813) when compared to the non-CLIL group (640) and both groups were under the 1,000 most frequent words in English. The standard deviations are quite alike, although the CLIL cohort presents greater variability in their scores and their deviations are slightly higher when compared to the non-CLIL cohort (327 vs 304)

Table 3. Estimation of words CLIL and non-CLIL groups.

Kolmogorov-Smirnov and Shapiro Wilk tests were implemented in order to ascertain whether our sample met the normality assumption. The values obtained (see table 4) indicate their distribution is not normal for the variable type of instruction, therefore non-parametric tests had to be implemented.

*Table 5. Non-parametric tests: Type of instruction*

The results for our third research question (Do we find statistically significant differences in students’ performance with regard to sex and type of instruction in the Productive Vocabulary Levels Test?), CLIL girls obtained better maximum scores (29 points) in the PVLT whereas non-CLIL boys attained the highest rate in the lowest scale of the rank (i.e. 0-5 points). As can be seen in Figure 2, most of the informants, regardless of their sex and type of instruction scored between 6-10 points in the productive vocabulary test. With regard to medium scale of the rank (i.e. 11-15 points), non-CLIL and CLIL girls obtained the highest percentages (33%). On the contrary, CLIL boys are much better in regards to the 16-20 point rank (24% vs. 11%). Finally, 5% of non-CLIL and CLIL boys scored more than 20 points but less than 25 in the PVLT. As we will analyse in the following section, these findings show the tendency that boys and girls behave similar to peers of their same sex regardless of the type of instruction.

*Figure 2. Frequency distribution of tests scores for boys and girls.*

The box-plot in figure 3 illustrates graphically the median values for boys and girls in both types of instruction, which concord with the data analysed above. This figure also indicates that our results are quite homogeneous for both cohorts. There is also an outlier which belongs to a girl whose scores are much higher than the ones obtained by the rest of the students. She belongs to the CLIL group and is the informant who scored 29 points in the PVLT:

Figure 3. Median values according to sex and type of instruction.

Regarding word estimates and sex-based differences, the descriptive statistics shown in Table 6 illustrate that non-CLIL boys obtained the lowest mean scores (635 words) closely followed by non-CLIL girls (661 words). One CLIL girl obtained the highest score (1933 words), but CLIL boys attained the highest mean score (876 words).

Table 6. Distribution of word estimates according to sex.

Kolmogorov-Smirnov and Shapiro-Wilk parametric tests were implemented in order to ascertain whether our sample met the normality assumption according to sex based differences. As shown in Table 7, the p-values obtained were lower than (p=0.05) for the girls, so the sample did not meet normality and, therefore, non-parametric tests were applied.

6. Discussion

The analysis of our data clearly shows that, regardless of the type of instruction (i.e. CLIL/non-CLIL), the productive vocabulary knowledge of the 10th graders analysed in the present research is lower than 1,000 words. If we compare this data with the findings obtained by Moreno Espinosa (2010) in the same educational level and socio-cultural context, we ascertain that productive vocabulary size is practically the same for both non-CLIL samples of students since our students’ estimation of words is 640 and Moreno Espinosa’s 645. These results may also imply that the EFL instruction Moreno Espinosa’s and our sample of non-CLIL groups of learners have received in the compulsory schooling, is rather similar, regardless of the type of school students have attended.

Our data also indicates that CLIL learners obtained significantly higher scores than non-CLIL students in the PVL T (p=0.014), which seems to show that CLIL instruction may favour productive vocabulary learning. This result is in line with previous studies, which show that CLIL or longer foreign language exposure programs foster vocabulary learning, and that benefits start appearing after some time (Agustin Llach and Canga Alonso, 2014; Celaya & Ruiz de Zarobe, 2010). The longer exposure to English input CLIL learners have received can help explain this advantage in general productive vocabulary size. Furthermore, the different nature of their exposure, in which traditional EFL instruction is combined with a more meaningful and contextualized content instruction through the L2 might also account for this difference (Xanthou, 2011). As an avenue for further research, future studies could test learners productive knowledge of specific vocabulary related to certain fields such as Natural Sciences and/or Arts and Crafts (the CLIL subjects). We could speculate that results would favour the CLIL group, whose productive vocabulary size might be higher for both semantic fields. However, this is just mere speculation, since we have not conducted such test and further research on words students may have acquired in the content classes together with a comparison of their results to non-CLIL learners’ is needed.

In short, CLIL seems to favour productive vocabulary knowledge, but there might be other factors influencing students’ productive vocabulary learning, such as exposure time. It is indeed difficult to discern whether the CLIL factor or the longer exposure (more instruction hours) is responsible for the CLIL advantage in our data, as these two factors are impossible to untangle in our present study.
If we compare our findings with previous studies on receptive vocabulary size conducted in the same area and educational level but with a different sample of students Canga Alonso (2013c), we ascertain that the estimations of words are higher in the receptive vocabulary test (935 words). These results concord with previous research on students’ receptive and productive vocabulary sizes as students tend to obtain better results in receptive tests than in productive ones because reception is a prior step to production (Zhong, 2012; Yamamoto 2011; Martínez Adrián & Gallardo del Puerto, 2010; Webb 2008; Lauffer, 1998). However, this comparison should be taken with caution since Canga Alonso has not conducted research on productive vocabulary knowledge and his sample of students is different from the one analysed in the present study. As abovementioned, research has shown that receptive skills are developed prior to productive ones which explains that students’ results in the receptive VLT were higher. Therefore, further research is called to correlate the receptive and productive vocabulary of the students in the present sample to compare it with previous studies on receptive and productive vocabulary in the same area.

Our results also indicate that CLIL and non-CLIL learners would have problems in performing certain linguistic tasks such as understanding informal spoken discourse for which Adolphs & Schmitt (2004) estimate that, at least, 2,000 words are needed. Nation (2006) talks of 6,000 to 7,000 word families for comprehension of spoken text, if 98% coverage of a text is desired for understanding written text, and he contends that 8,000 to 9,000 word families are needed for text understanding, or for reading for pleasure. Nevertheless, EFL learners would have an easier time watching TV programmes (Webb & Rogers 2009a), or movies (Webb & Rogers 2009b), since the first 1,000 most frequent words make up for around 85% of the total word coverage. Accordingly, researchers call for the command of the 2,000-3,000 most frequent words as soon as possible (Webb and Chang 2012; Nation & Waring, 1997; Nation, 1993), and our students’ mean scores (813 vs 640 words) indicates that they have not even acquired the 1,000 most frequent words in English. Furthermore, we agree with Schmitt (2000) and Webb & Chang (2012) that such a paramount learning task cannot be left to chance and that the most frequent words should be taught explicitly in the EFL classroom.

Sex-based differences are non-significant in the present study (p=0.13) although CLIL boys obtained the highest scores (876 words). This finding is in line with the results obtained in receptive vocabulary with students of their same age in non-CLIL instruction (Canga Alonso, 2013c), but differs from tests with younger CLIL and non-CLIL learners in their same educational context (Canga Alonso, 2013a, 2013b; Agustín Llach and Terrazas Gallego, 2012; Jiménez Catalán and Terrazas Gallego, 2005-2008) where girls obtained the highest scores. It is also noteworthy that the sample of CLIL students shows the opposite tendency since non-CLIL girls slightly outperformed non-CLIL boys (661 vs. 635 words) and followed CLIL girls (748 vs. 661 words). In light of these results on sex-based differences and type of instruction, we agree with Sunderland’s (2010) assertion that the relationships between vocabulary and sex are not enduring, but may be context and test type-specific, and also influenced by L2 proficiency since by implementing the same test (i.e. PVLT parallel version A+C) in the same context (i.e. last year of Spanish compulsory education) students obtained different results according to their sex and type of instruction. In this way, male CLIL learners obtained the highest scores whereas non-CLIL girls outperformed their male non-CLIL partners. These similar results for both sexes also verify our initial presupposition that sex-based scores should be similar since both sexes were treated equally in the classroom and they received the same formal instruction.
All in all, this data indicates that CLIL instruction has been beneficial for the CLIL group. However, we should take this assumption with caution since the sample of CLIL learners is not very numerous and further research is needed in order to test if a bigger sample of CLIL students would obtain similar results to the ones shown in this paper.

7. Conclusions

Three main findings stand out from the present research study. First, the productive vocabulary size of our sample of Spanish secondary school CLIL and non-CLIL learners lies below the range of first 1,000 most frequent words in English, according to the results of the PVLT, which shows that our students might find it difficult to understand spoken and written texts in English. As expected, their scores are lower to those obtained by students of their same age and sociocultural background in receptive vocabulary tests since reception is a previous step to production when you learn a foreign language. With regard to the second research question, the results purport that CLIL instruction seems to favour larger productive vocabulary sizes as CLIL learners obtained significantly better results than non-CLILs. Finally, no statistically significant differences can be established according to the sex of the participants, which implies that boys and girls have added a similar amount of words to their productive vocabulary. Nevertheless, these results should be taken with caution due to the number of students who took part in the present research. Therefore, further research is needed in order to explore if the productive vocabulary size of a bigger sample of students of the same age and types of instruction from different schools in the area remains alike or is significantly higher or lower than our informants’ productive vocabulary knowledge. One further limitation of the present study is the use of a single, and somewhat limited, instrument to measure productive vocabulary size. Using other tests for vocabulary knowledge, such as lexical availability tests might provide even more insightful results and reveal more qualitative data concerning learners’ vocabulary knowledge. Finally, CLIL programmes have spread in Spain in the last decade; therefore it would be interesting to relate 10th graders receptive and productive vocabulary knowledge in order to ascertain which type of instruction (CLIL/non-CLIL) could benefit vocabulary learning. Further research is called for to overcome these limitations and address this new research path on CLIL instruction.

__Andrés Canga Alonso__ holds a PhD in English Philology and is currently a lecturer at the University of La Rioja. His research focuses on the applications of e-mail tandem and autonomy in mixed-ability EFL learners, the analysis of receptive and productive vocabulary of primary and secondary CLIL and non-CLIL learners, and the use of language portfolios in EFL and translation. He has published several articles in scientific journals on the abovementioned fields, and is a member of GLAUR research group.

__Mario Arribas García__ is an EFL teacher in a secondary school, a CLIL researcher, and teacher trainer. He is currently finishing his PhD thesis focused both on vocabulary teaching and learning in CLIL and EFL contexts, and the differences between CLIL and EFL textbooks and teaching materials. He has also published previous articles about vocabulary acquisition.

In the following sentences we have omitted the end of a word. Complete the sentences with the right word. For examples: *He was riding a bicycle*; you should have completed the sentence as follows: *He was riding a bicycle*.

The 2,000-word level
Example: He was riding a bicycle.

1. They will restore the house to its ___ state.
2. Each room has its own ___ bath and WC.
3. The ___ number of students at the university is 12,347.
4. They met to ___ a president.
5. Many companies were ___ computers.
6. The lakes become ice-free and the snow ___ .
7. They managed to steal his ___ some knives.
8. I asked the group to invite her to the party.
9. She shouted at him for spoiling her lovely evening.
10. You must spend less until your debts are paid.
11. His mother looked at him and loved him.
12. The wind roared through the forest.
13. There was frost and blood everywhere.
14. She earns a high salary as a lawyer.
15. The sick child had a very high temperature.
16. The birth of her first child was a difficult time.
17. My favourite sport is football.
18. In A.D. 636 an Arab army won a famous victory over another army.
19. I'm glad we had this opportunity to talk.
20. There are a dozen eggs in the basket.
21. Every working person must pay income tax.
22. The pirates buried the treasure on a desert island.
23. Her beauty and charm had a powerful effect on men.
24. Lack of rain led to a shortage of water in the city.
25. He takes sugar and sugar in his coffee.
26. Pupils must hand in their papers by the end of the week.
27. Ann introduced her boyfriend to her mother.
28. Teenagers often admire and worship pop singers.
29. In order to be accepted into the university, he had to improve his grades.
30. The dress you're wearing is too ....
